3 Introduction

The following document details the Module Interface Specifications for SynthEddy, a software to artificially generate flow field that mimics turbulent flow, which can be use as starting point for CFD simulation.

Complementary documents include the System Requirement Specifications and Module Guide. The full documentation and implementation can be found at [SRS](#), [MG](#).

4 Notation

The structure of the MIS for modules comes from [Hoffman and Strooper \(1995\)](#), with the addition that template modules have been adapted from [Ghezzi et al. \(2003\)](#). The mathematical notation comes from Chapter 3 of [Hoffman and Strooper \(1995\)](#). For instance, the symbol $:=$ is used for a multiple assignment statement and conditional rules follow the form $(c_1 \Rightarrow r_1 | c_2 \Rightarrow r_2 | \dots | c_n \Rightarrow r_n)$.

The following table summarizes the primitive data types used by SynthEddy.

Data Type	Notation	Description
character	char	a single symbol or digit
integer	\mathbb{Z}	a number without a fractional component in $(-\infty, \infty)$
natural number	\mathbb{N}	a number without a fractional component in $[1, \infty)$
real	\mathbb{R}	any number in $(-\infty, \infty)$

The specification of SynthEddy uses some derived data types: sequences, strings, and tuples. Sequences are lists filled with elements of the same data type. Strings are sequences of characters. Tuples contain a list of values, potentially of different types. In addition, SynthEddy uses functions, which are defined by the data types of their inputs and outputs. Local functions are described by giving their type signature followed by their specification.

4.1 Variable Name Traceability

To help program development and understanding, several concepts regarding the eddy profile from the SRS TM and DD are renamed in the MIS to better reflect their usage in the code:

- radius: length-scale (σ) of the eddy. Since the eddy vorticity distribution is cut-off outside the length-scale, they are essentially spheres in 3D space [SRS: TM1].
- strength: magnitude of the eddy intensity vector (α) [SRS: DD3].
- orient: unit vector direction of the eddy intensity vector (α) [SRS: DD3].

4.2 Abstract Data Types

As several modules listed in Section 5 are Abstract Data Types (ADTs), this documents use their types as follows:

- VectorT: 3-element NumPy array \mathbb{R}^3 , representing a 3D position or velocity vector and vector/matrix operation methods [MG: M7].
- EddyT: Eddy object, stores eddy strength, radius orient and position information, with methods for velocity calculation, see Eddy Module [MIS10].
- EddyProfileT: Eddy profile object, stores a Record of different types of eddies with their parameters (strength, radius), and weights for random generation [MIS8].
- FlowFieldT: Flow field object, stores all EddyT objects in that field, with methods for velocity sum calculation, see Flow Field Module [MIS9].

5 Module Decomposition

The following table is taken directly from the Module Guide document for this project.

Level 1	Level 2
Hardware-Hiding Module	
Behaviour-Hiding Module	Main Control Module
	Query Interface
	Eddy Profile Module
	Flow Field Module
	Eddy Module
Software Decision Module	Shape Function Module
	File I/O Module
	Vector Module
	Visualization Module

Table 1: Module Hierarchy

6 MIS of Main Control Module

6.1 Module

main

6.2 Uses

- Query Interface [MIS7]
- Flow Field Module [MIS9]
- Eddy Profile Module [MIS10]

6.3 Syntax

6.3.1 Exported Constants

None.

6.3.2 Exported Access Programs

Name	In	Out	Exceptions
main	command_args str,	-	-

6.4 Semantics

6.4.1 State Variables

None.

6.4.2 Environment Variables

- Command line console.

6.4.3 Assumptions

None.

6.4.4 Access Routine Semantics

main(command_args):

- `--new_field --name <field_name> --dim <Lx>,<Ly>,<Lz>, --vel <avg_vel> --count <eddy_count> --profile <profile_name>`
 - call `eddy_profile.load(profile_name)` to read the eddy profile file.

- call `flow_field.init(profile, field_name, dimensions, avg_vel, eddy_count)` to create a new flow field.
- `--field <field_name> --query <request>`
 - call `flow_field.load(field_name)` to load the flow field.
 - call `query.handle_request(request)` to get the velocity vectors at the queried points.

6.4.5 Local Functions

None.

7 MIS of Query Interface

7.1 Module

query

7.2 Uses

- Flow Field Module [MIS9]

7.3 Syntax

7.3.1 Exported Constants

None.

7.3.2 Exported Access Programs

Name	In	Out	Exceptions
handle_request	request str	response str	InvalidRequestFormat

7.4 Semantics

7.4.1 State Variables

None.

7.4.2 Environment Variables

None.

7.4.3 Assumptions

None.

7.4.4 Access Routine Semantics

handle_request(request):

Decode the request string and call the Flow Field Module to get the velocity vectors at the queried positions and times.

- transition:
 - decode(request) to get the positions and times $\{\{\text{VectorT}, \mathbb{R}\}\}$ to be queried.

- call `flow_field.sum_vel(position, time)` to get the final velocity vector at each position/time, and put them in the response array `{VectorT}`.
- output: `out := encode({VectorT})`, velocity vectors at all the queried points in one JSON string.
- exception: `exc := (decode(request) is not {VectorT} \Rightarrow InvalidRequestFormat)`, the request should be a JSON string of positions vectors to query get the velocity vectors.

More request methods to be implemented in the future.

7.4.5 Local Functions

`decode(request):`

- output: `out := {VectorT}`, an array of position vectors.

`encode(response):`

- output: `out := JSON string of the response array`.

8 MIS of Eddy Profile Module

8.1 Module

eddy_profile

8.2 Uses

- File I/O Module [MIS12]

8.3 Syntax

8.3.1 Exported Constants

None.

8.3.2 Exported Access Programs

Name	In	Out	Exceptions
load	profile_name str	-	InvalidProfile
get_params	-	params $\{\{\mathbb{R}+, \mathbb{R}+\}\}$	-
get_weights	-	weights $\{\mathbb{R}+\}$	-

8.4 Semantics

8.4.1 State Variables

- **name:** str, name of the eddy profile (is also filename).
- **params:** $\{\{\mathbb{R}+, \mathbb{R}+\}\}$, array of {strength, radius} sets for each type of eddy.
- **weights:** $\{\mathbb{R}+\}$, corresponding array of weights for each type of eddy.

8.4.2 Environment Variables

None.

8.4.3 Assumptions

None.

8.4.4 Access Routine Semantics

`load(profile_name):`

Load a saved eddy profile from file, which contains the one or more eddy types, their parameters (intensity magnitude and length-scale) and weights (for random generation).

- transition: `params, weights := fileIO.read('profile', profile_name)`
- exception: `exc := (params is not $\{\{\mathbb{R}^+, \mathbb{R}^+\}\}$ or weights is not type $\{\mathbb{R}^+\} \Rightarrow \text{InvalidProfile}$)`

`get_params():`

- output: `out := params`

`get_weights():`

- output: `out := weights`

8.4.5 Local Functions

Some functions to compute the eddy profile based on user provided parameters, to be implemented in the future.

9 MIS of Flow Field Module

9.1 Module

`flow_field`

9.2 Uses

- Eddy Module [MIS10]
- Vector Module [NumPy]
- File I/O Module [MIS12]
- Visualization Module [MIS13] (PLACEHOLDER)

9.3 Syntax

9.3.1 Exported Constants

None.

9.3.2 Exported Access Programs

Name	In	Out	Exceptions
init	profile EddyProfileT, field_name str, dimensions VectorT, avg_vel \mathbb{R} , eddy_count \mathbb{Z}	-	InvalidDimensions InvalidAvgVelocity EddyScaleTooLarge
load	field_name str	-	-
save	-	field Record	-
sum_vel	position VectorT, time \mathbb{R}	velocity VectorT	OutOfBoundary NegativeTime

9.4 Semantics

9.4.1 State Variables

- **profile:** EddyProfileT, eddy profile to be used to generate the flow field.
- **name:** str, name of the flow field (is also filename).
- **dimensions:** VectorT of $\{L_x, L_y, L_z\}$, size of the flow field, with x being the axial direction, y vertical and z horizontal.
- **avg_vel:** \mathbb{R} , average flow velocity along x-axis.

- eddies: {EddyT}, array of eddies in the flow field.

9.4.2 Environment Variables

None.

9.4.3 Assumptions

- External flow [SRS: A4, MG: AC2]

9.4.4 Access Routine Semantics

`init(profile, field_name, dimensions, avg_vel, eddy_count):`

Initialize the flow field with given eddy profile. Randomly generate eddies based on their parameters and associated weights, and give them initial positions within the flow field.

- transition:
 - `profile, name, length_x, length_y, length_z, avg_vel` := as inputted
 - `eddies` := {`eddy_count` number of EddyT randomly generated with `profile`}
- exception:
 - `exc` := (any of `d` in `dimensions` $\leq 0 \Rightarrow$ InvalidDimensions)
 - `exc` := (`avg_vel` $< 0 \Rightarrow$ InvalidAvgVelocity)
 - `exc` := (any of $2 * \{\text{radius in profile}\} \geq$ any of `d` in `dimensions` \Rightarrow EddyScaleTooLarge)

`load(field_name):`

- transition: all state variables reconstructed from `fileIO.read('field', field_name)`.

`save(new_name?):`

- transition: `name` := `new_name` if provided, otherwise name remains the same.
- output: `out` := Record (dict) with all current state variables. Each EddyT in `eddies` is also converted to a Record. So that `fileIO.write('field', Record)` can be called to serialized the current state of the flow field into a JSON string for saving.

`sum_vel(position, time):`

Add up the velocity influence from all eddies at a given position and time.

- output: `out` := $\sum \{\text{eddy.get_vel}(\text{position} - \text{eddy_pos}(\text{eddy}, \text{time})) \text{ for each eddy in eddies}\}$, with wrap-around applied for eddies near the boundary.

9.4.5 Local Functions

`eddy_pos(eddy, time):`

- output: `out := VectorT: {
 get_offset(time) + eddy.get_init_x(),
 eddy.get_y(get_iter(time), dimensions[1]),
 eddy.get_z(get_iter(time), dimensions[2])
}`, the center position of the eddy at a given time (moving due to flow).

`get_iter(time):`

- output: `out := round($\frac{\text{avg_vel} * \text{time}}{\text{dimensions}[0]}$)`, the number of iterations of the flow field at a given time (how many x-lengths have passed due to average flow velocity).

`get_offset(time):`

- output: `out := avg_vel * time % dimensions[0]`, the x-offset of the flow field at given time in current iteration.

10 MIS of Eddy Module

10.1 Module

eddy

10.2 Uses

- Shape Function Module [MIS11]

10.3 Syntax

10.3.1 Exported Constants

None.

10.3.2 Exported Access Programs

Name	In	Out	Exceptions
init	field_dimensions VectorT, strength $\mathbb{R}+$, radius $\mathbb{R}+$, orient VectorT	-	-
get_init_x	-	init_x \mathbb{R}	-
get_y	iter \mathbb{Z} , length_y $\mathbb{R}+$	y \mathbb{R}	-
get_z	iter \mathbb{Z} , length_z $\mathbb{R}+$	z \mathbb{R}	-
get_vel	rel_position VectorT	velocity VectorT	-

10.4 Semantics

10.4.1 State Variables

- **init_x**: \mathbb{R} , the initial offset from zero x-position.
- **strength**: $\mathbb{R}+$, intensity of the eddy.
- **radius**: $\mathbb{R}+$ for length scale. Velocity outside of **radius** is always zero.
- **orient**: VectorT, unit vector describing the orientation of the eddy spin axis.
- **y_arr**: $\{\mathbb{R}\}$, array of y-positions at each flow iteration.
- **z_arr**: $\{\mathbb{R}\}$, array of z-positions at each flow iteration.

10.4.2 Environment Variables

None.

10.4.3 Assumptions

- EddyT objects are not created manually, but generated by calls from `flow_field`. Thus, the caller has ensured the validity of all parameters.

10.4.4 Access Routine Semantics

`init(init_x, strength, radius, orient):`

Initialize the eddy object to give it strength, radius and orientation, and random initial position. The initial position is generated for 3 flow field iterations, so that wrap-around can be applied at inlet and outlet from the beginning.

- transition:
 - `strength, radius, orient := as inputted`
 - `init_x := rand(0, field_dimensions[0])`
 - `y[0], y[1], y[2] := {rand(0, field_dimensions[1])}`
 - `z[0], z[1], z[2] := {rand(0, field_dimensions[2])}`

`get_init_x():`

- output: `out := init_x`

`get_y(iter, length_y):`

- transition: `y[iter] := rand(0, length_y)` if `y[iter]` does not exist.
- output: `out := y[iter]`

`get_z(iter, length_z):`

- transition: `z[iter] := rand(0, length_z)` if `z[iter]` does not exist.
- output : `out := z[iter]`

`get_vel(rel_position):`

Get the velocity influence due to this eddy at a given position relative to the eddy center.

- output: `out := computed from rel_position with strength, radius, orient and ShapeFunction.active(rel_position, radius)`, see [SRS: TM1, GM1]

`dump():`

- output: `out := Record of all current state variables. Used by flow_field.save() to serialize the eddy object.`

10.4.5 Local Functions

None.

11 MIS of Shape Function Module

11.1 Module

shape_function

11.2 Uses

- Vector Module [NumPy]

11.3 Syntax

11.3.1 Exported Constants

None.

11.3.2 Exported Access Programs

Name	In	Out	Exceptions
set_active	active_func Function	-	-
active	rel_position VectorT, radius \mathbb{R}	shape_val \mathbb{R}	-
squared	rel_position VectorT, radius \mathbb{R}	shape_val \mathbb{R}	-
gaussian	rel_position VectorT, radius \mathbb{R}	shape_val \mathbb{R}	-
...	rel_position VectorT, radius \mathbb{R}	shape_val \mathbb{R}	-

User can modify this module to add more shape functions.

11.4 Semantics

11.4.1 State Variables

- **active**: The function that is currently designated as the active shape function.

11.4.2 Environment Variables

None.

11.4.3 Assumptions

None.

11.4.4 Access Routine Semantics

`set_active(active_func):`

- transition: `active := active_func`,
so that other modules can always call `shape_function.active()` to use the designated function. This should be set in `main` when the program starts.

`active():`

- output: `out := init_x`

`active(rel_position, radius):`

- output: `out := shape function value`, depending on the active shape function.

`squared(rel_position, radius):`

- output: `out := shape function value` computed by taking the distance from the `rel_position` to the center `mag(rel_position)`, and `radius` (or length `sclae`) of the eddy. See [SRS: TM1].

`gaussian(rel_position, radius):`

- output: `out := Use a different (gaussian) equation` to get the above value, as may be preferred by some researchers.

11.4.5 Local Functions

None.

12 MIS of File I/O Module

12.1 Module

fileIO

12.2 Uses

- Hardware Hiding Module [OS]

12.3 Syntax

12.3.1 Exported Constants

None.

12.3.2 Exported Access Programs

Name	In	Out	Exceptions
read	type str, name str	Record or Array	FileNotExist
write	type str, content Record or Array	-	FailToWrite

12.4 Semantics

12.4.1 State Variables

None.

12.4.2 Environment Variables

- Files on disk.

12.4.3 Assumptions

- The field name or profile name is the same as the filename.
- Saved fields are in `./fields/` and saved profiles are in `./profiles/` directories

12.4.4 Access Routine Semantics

read(type, name):

- output: `out := Record or Array`, the parsed content of the file.
- exception: `exc := (file cannot be found at ./<type>/<name>.json \Rightarrow FileNotExist)`

`write(type, content):`

- transition: write the serialized JSON string to the file on disk.
- exception: `exc := (file cannot be written to disk \Rightarrow FailToWrite)`

12.4.5 Local Functions

None.

13 MIS of Visualization Module

THIS IS A PLACEHOLDER [MG: AC5]

13.1 Module

visualize

13.2 Uses

- None

13.3 Syntax

[Extra information if required —SS]

15 Reflection

The information in this section will be used to evaluate the team members on the graduate attribute of Problem Analysis and Design. Please answer the following questions:

1. What are the limitations of your solution? Put another way, given unlimited resources, what could you do to make the project better? (LO_ProbSolutions)
2. Give a brief overview of other design solutions you considered. What are the benefits and tradeoffs of those other designs compared with the chosen design? From all the potential options, why did you select the documented design? (LO_Explores)
